

Finite Automata in Haskell

V. Velkey, W. Vromen

Saturday 13th May, 2023

Abstract

We give a toy example of a report in *literate programming* style. The main advantage of this is that source code and documentation can be written and presented next to each other. We use the listings package to typeset Haskell source code nicely.

1 How to use this?

To generate the PDF, open `report.tex` in your favorite $\text{\LaTeX}$ editor and compile. Alternatively, you can manually do `pdflatex report; bibtex report; pdflatex report; pdflatex report` in a terminal.

You should have stack installed (see <https://haskellstack.org/>) and open a terminal in the same folder.

- To compile everything: `stack build`.
- To open ghci and play with your code: `stack ghci`
- To run the executable from Section 3: `stack build && stack exec myprogram`
- To run the tests from Section 4: `stack clean && stack test --coverage`

2 DFA Implementation

This describes our implementation of Deterministic Finite State Automata. As in the definition, a DFA consists of a tuple $(Q, \Sigma, \delta, q_{start}, A)$ representing the set of states, the alphabet, the transition function, the start state and the accept states.

```
module DFA where

import Data.List()
import Data.Maybe()
type State = Int
type Symbol = Char
data DFA = DFA { states :: [State]
                , alphabet :: [Symbol]
                , delta :: State -> Symbol -> State
                , start :: State
                , acceptstate :: [State]}
```

We implement a basic evaluation function that upon input from the string, evaluates if the string is in the language.

```
evaluate :: DFA -> String -> Bool
evaluate df st = and (map ((flip $ elem) (alphabet df)) st) && (stateArr (start df) st) '
  elem' acceptstate df where
  stateArr :: State -> String -> State
  stateArr q [] = q
  stateArr q (x:xs) = stateArr (delta df q x) xs
```

We write a toy example DFA on the alphabet $\Sigma = \{0,1\}$ computing the language of words starting with a 0.

```
zeroStart :: DFA
zeroStart = DFA [0,1,2] ['0', '1'] deltazero 0 [1] where
  deltazero :: State -> Symbol -> State
  deltazero st char
  | st == 0 && char == '0' = 1
  | st == 0 && char == '1' = 2
  | st == 1 = 1
```

```
| st == 2 = 2
| otherwise = -1
```

This outputs:

```
ghci> evaluate zeroStart "010001"
True

ghci> evaluate zeroStart "1000110"
False

ghci> evaluate zeroStart []
False

ghci> evaluate zeroStart "0lakddkds1jkdjak"
False
```

Current implementation outputs 'false' for words containing characters outside the alphabet.

3 Wrapping it up in an executable

We will now use the library from Section 2 in a program.

```
module Main where

import DFA
import Data.List()
import Data.Maybe

main:: IO ()
main = undefined
```

The output of the program is something like this:

```
Hello!
[1,2,3,4,5,6,7,8,9,10]
[100,100,300,300,500,500,700,700,900,900]
[1,3,0,1,1,2,8,0,6,4]
[100,300,42,100,100,100,700,42,500,300]
GoodBye
```

Note that the above `showCode` block is only shown, but it gets ignored by the Haskell compiler.

4 Simple Tests

We now use the library QuickCheck to randomly generate input for our functions and test some properties.

```
module Main where

import Basics

import Test.Hspec
import Test.QuickCheck
```

The following uses the HSpec library to define different tests. Note that the first test is a specific test with fixed inputs. The second and third test use QuickCheck.

```
main :: IO ()
main = hspec $ do
  describe "Basics" $ do
    it "somenumbers should be the same as [1..10]" $
      somenumbers 'shouldBe' [1..10]
    it "funnyfunction: result is within [1..100]" $
      property (\n -> funnyfunction n 'elem' [1..100])
    it "myreverse: using it twice gives back the same list" $
      property $ \str -> myreverse (myreverse str) == (str::String)
```

To run the tests, use `stack test`.

To also find out which part of your program is actually used for these tests, run `stack clean && stack test`. Then look for “The coverage report for ... is available athtml” and open this file in your browser. See also: https://wiki.haskell.org/Haskell_program_coverage.

5 Optional: Profiling

The GHC compiler comes with a profiling system to keep track of which functions are executed how often and how much time and memory they take. To activate this RTS, we compile and execute our program as follows:

```
stack clean
stack build --profile
stack exec --profile myprogram -- +RTS -p
```

Results are saved in the file `myprogram.prof` which looks as follows. Note for example, that `funnyfunction` was called on 14 entries.

COST CENTRE	MODULE	no. entries		individual		inherited	
				%time	%alloc	%time	%alloc
MAIN	MAIN	227	0	0.0	0.8	0.0	100.0
main	Main	455	0	0.0	29.6	0.0	38.6
funnyfunction	Basics	518	14	0.0	0.6	0.0	0.6
randomnumbers	Basics	464	0	0.0	0.3	0.0	8.4
randomRIO	System.Random	468	0	0.0	0.0	0.0	8.0
...							

For many more RTS options, see the GHC documentation online at https://downloads.haskell.org/~ghc/latest/docs/html/users_guide/profiling.html.

6 Conclusion

Finally, we can see that [LW13] is a nice paper.
